

STOP THE SPREAD OF HANTAVIRUS

What is the Hantavirus?

The Hantavirus is a disease that affects people worldwide. This disease can cause two different syndromes, hantavirus pulmonary syndrome (HPS) and hemorrhagic fever with renal syndrome (HFRS). It was first discovered and researched in North Korea and South Korea, and then spread throughout Europe, Asia, and eventually reached the United States.

Symptoms

Hantavirus Pulmonary Syndrome (HPS):

- fatigue, fever, muscle aches, headaches, dizziness, chills, abdominal problems, coughing, shortness of breath, and might experience tightness in the chest.

Hemorrhagic Fever with Renal Syndrome (HFRS):

- intense headaches, back and abdominal pain, fever/chills, nausea, blurred vision, flushing of the face, inflammation or redness of the eyes, a rash, low blood pressure, lack of blood flow, internal bleeding, and acute kidney failure.

Transmission

The Hantavirus is a zoonotic disease, meaning it is an infectious disease that can be transmitted from animals to humans. Specifically, hantavirus is a disease that is transmitted from breathing in or coming in contact with infected rodent urine, droppings, or saliva.

Treatments

There is no specific treatment for Hantavirus. Recommendations include to rest, hydrate, and receive supportive care. HPS causes difficulty breathing, so patients may need breathing support. HFRS disrupts kidney functions so patients may need dialysis to remove toxins from the blood.

Places of Risk

Places with high risk areas of hantavirus include, Southwestern and Western U.S. States. States such as New Mexico, Arizona, Colorado, Utah, California, Montana, Washington, Idaho, Wyoming, and Oregon.
